# Data Mining Cluster Analysis: Basic Concepts and Algorithms Lecture Notes for Chapter 8 Introduction to Data Mining by Tan, Steinbach, Kumar

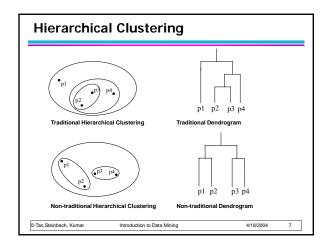

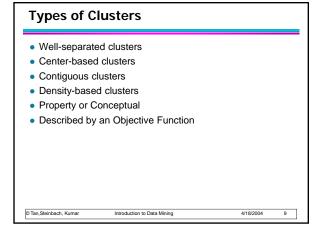

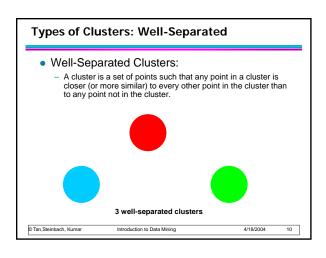

### Exclusive versus non-exclusive In non-exclusive clustering, points may belong to multiple clusters. Fuzzy versus non-fuzzy In fuzzy clustering, a point belongs to every cluster with some weight between 0 and 1 Weights must sum to 1 Probabilistic clustering has similar characteristics Partial versus complete In some cases, we only want to cluster some of the data Heterogeneous versus homogeneous Cluster of widely different sizes, shapes, and densities

### **Clustering Algorithms**

- K-means and its variants
- Hierarchical clustering
- Density-based clustering

© Tan, Steinbach, Kumar Introduction to Data Mining 4/18/2004 15

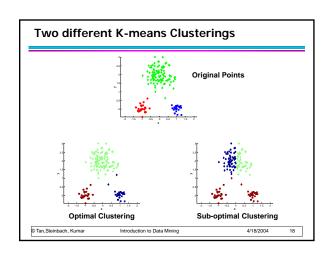

### K-means Clustering

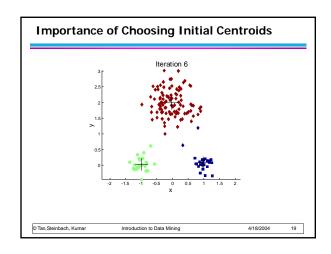

- Partitional clustering approach
- Each cluster is associated with a centroid (center point)
- Each point is assigned to the cluster with the closest centroid
- Number of clusters, K, must be specified
- The basic algorithm is very simple
- Select K points as the initial centroids.
- 2: repeat
- 3: Form K clusters by assigning all points to the closest centroid.
- 4: Recompute the centroid of each cluster.
- 5: until The centroids don't change

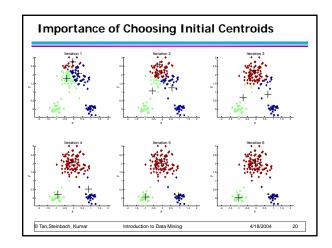

© Tan, Steinbach, Kumar Introduction to Data Mining 4/18/2004 16

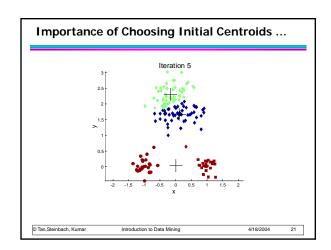

### K-means Clustering - Details

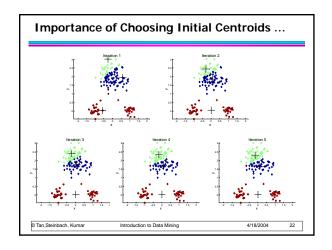

- Initial centroids are often chosen randomly.
  - Clusters produced vary from one run to another.
- The centroid is (typically) the mean of the points in the cluster.
- 'Closeness' is measured by Euclidean distance, cosine similarity, correlation, etc.
- K-means will converge for common similarity measures mentioned above.
- Most of the convergence happens in the first few iterations.
  - Often the stopping condition is changed to 'Until relatively few points change clusters'
- Complexity is O( n \* K \* I \* d )
  - n = number of points, K = number of clusters,
     I = number of iterations, d = number of attributes

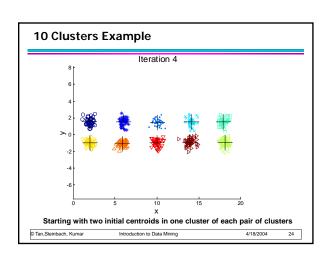

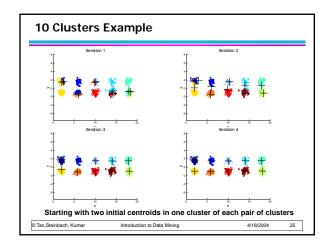

### **Evaluating K-means Clusters**

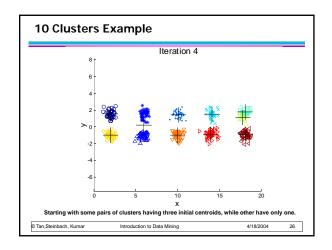

- Most common measure is Sum of Squared Error (SSE)
  - For each point, the error is the distance to the nearest cluster
  - To get SSE, we square these errors and sum them.

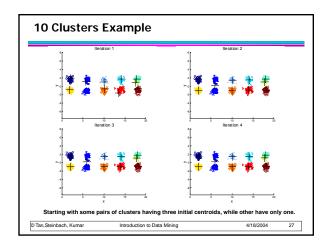

$$SSE = \sum_{i=1}^{K} \sum_{x \in C_i} dist^2(m_i, x)$$

- x is a data point in cluster  $C_i$  and  $m_i$  is the representative point for cluster  $C_i$
- can show that m<sub>i</sub> corresponds to the center (mean) of the cluster
- Given two clusters, we can choose the one with the smallest
- One easy way to reduce SSE is to increase K, the number of
  - ♦ A good clustering with smaller K can have a lower SSE than a poor clustering with higher K

## Multiple runs Helps, but probability is not on your side Sample and use hierarchical clustering to determine initial centroids Select more than k initial centroids and then select among these initial centroids Select most widely separated Postprocessing Bisecting K-means Not as susceptible to initialization issues

### **Handling Empty Clusters**

- Basic K-means algorithm can yield empty clusters
- Several strategies
  - Choose the point that contributes most to SSE
  - Choose a point from the cluster with the highest SSE
  - If there are several empty clusters, the above can be repeated several times.

### **Pre-processing and Post-processing**

Introduction to Data Mining

4/18/2004

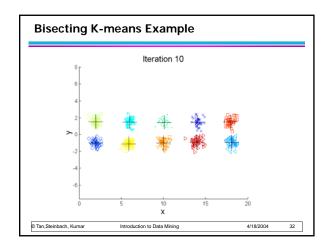

28

Pre-processing

© Tan,Steinbach, Kumar

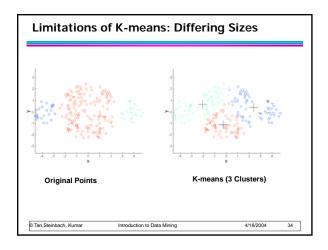

- Normalize the data
- Eliminate outliers
- Post-processing
  - Eliminate small clusters that may represent outliers
  - Split 'loose' clusters, i.e., clusters with relatively high SSE
  - Merge clusters that are 'close' and that have relatively low SSE
  - Can use these steps during the clustering process

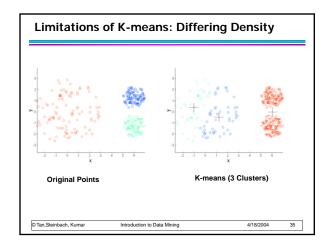

# Bisecting K-means Bisecting K-means algorithm Variant of K-means that can produce a partitional or a hierarchical clustering I: Initialize the list of clusters to contain the cluster containing all points. repeat Select a cluster from the list of clusters for i = 1 to number\_of\_iterations do Bisect the selected cluster using basic K-means end for Add the two clusters from the bisection with the lowest SSE to the list of clusters. until Until the list of clusters contains K clusters Data, Steinbach, Kumar Introduction to Data Mining 4/18/2004 31

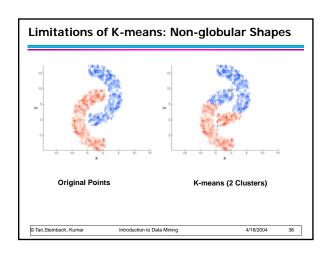

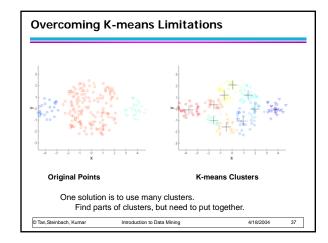

### **Limitations of K-means**

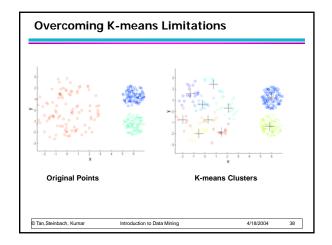

- K-means has problems when clusters are of differing
  - Sizes
  - Densities
  - Non-globular shapes
- K-means has problems when the data contains outliers.

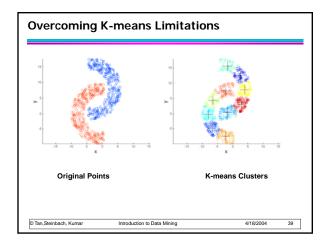

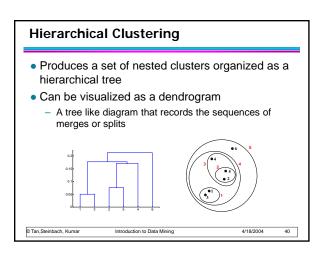

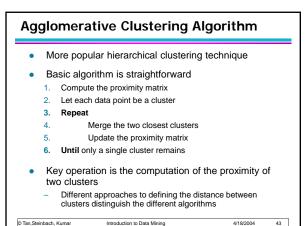

### Strengths of Hierarchical Clustering

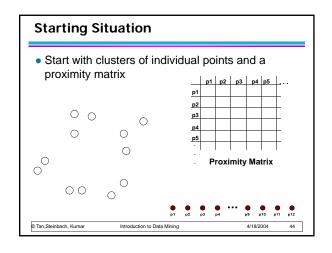

- Do not have to assume any particular number of clusters
  - Any desired number of clusters can be obtained by 'cutting' the dendogram at the proper level
- They may correspond to meaningful taxonomies
  - Example in biological sciences (e.g., animal kingdom, phylogeny reconstruction, ...)

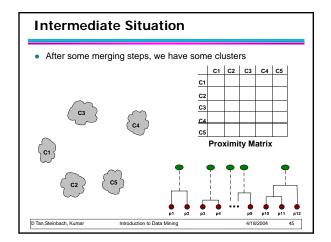

© Tan,Steinbach, Kumar Introduction to Data Mining 4/18/2004 41

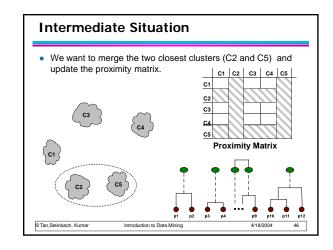

### **Hierarchical Clustering**

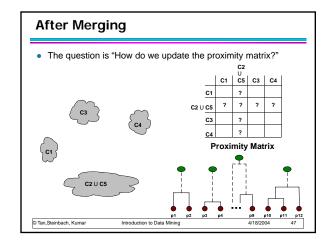

- Two main types of hierarchical clustering
  - Agglomerative:
    - Start with the points as individual clusters
       At each step, merge the closest pair of clusters until only one cluster (or k clusters) left
  - Divisive:
    - Start with one, all-inclusive cluster
    - At each step, split a cluster until each cluster contains a point (or there are k clusters)
- Traditional hierarchical algorithms use a similarity or distance matrix
  - Merge or split one cluster at a time

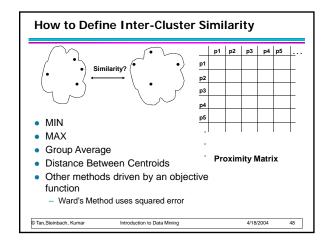

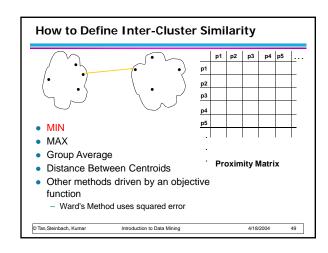

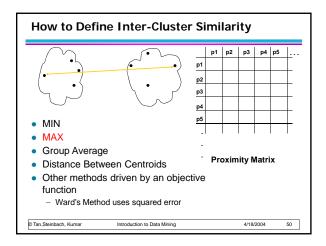

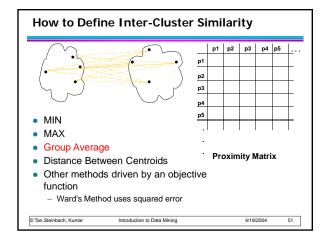

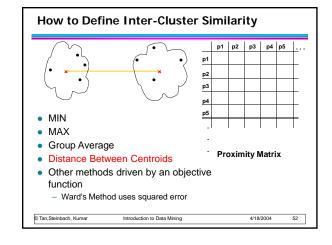

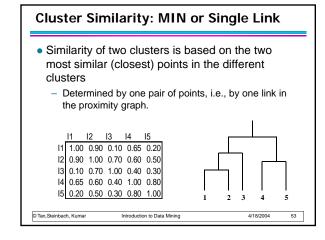

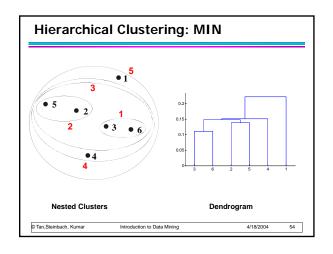

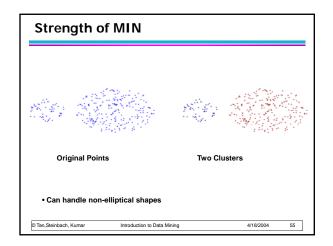

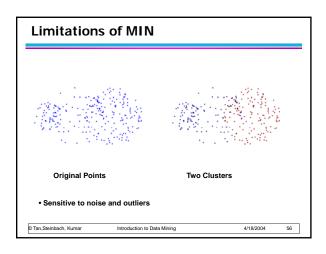

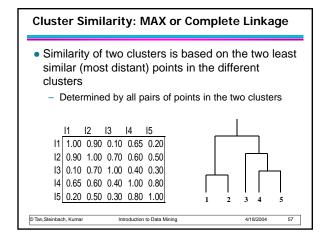

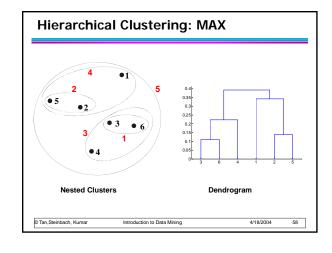

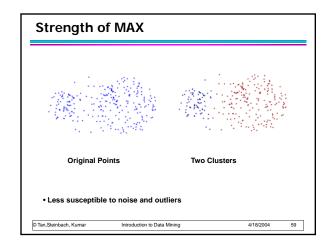

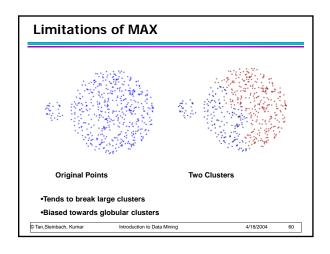

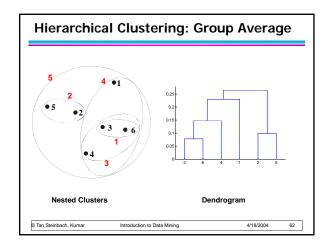

### 

### **Hierarchical Clustering: Group Average**

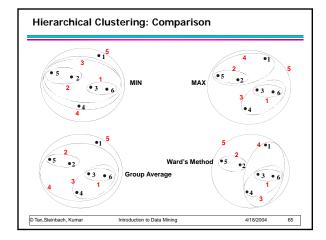

- Compromise between Single and Complete Link
- Strengths
  - Less susceptible to noise and outliers
- Limitations
  - Biased towards globular clusters

© Tan, Steinbach, Kumar Introduction to Data Mining 4/18/2004 63

### Cluster Similarity: Ward's Method

- Similarity of two clusters is based on the increase in squared error when two clusters are merged
  - Similar to group average if distance between points is distance squared
- Less susceptible to noise and outliers
- Biased towards globular clusters
- Hierarchical analogue of K-means
  - Can be used to initialize K-means

© Tan, Steinbach, Kumar Introduction to Data Mining 4/18/2004 64

### O(N²) space since it uses the proximity matrix. N is the number of points.

Hierarchical Clustering: Time and Space requirements

- O(N³) time in many cases
  - There are N steps and at each step the size, N<sup>2</sup>, proximity matrix must be updated and searched
  - Complexity can be reduced to  $O(N^2 \, log(N)$  ) time for some approaches

### Hierarchical Clustering: Problems and Limitations

- Once a decision is made to combine two clusters, it cannot be undone
- No objective function is directly minimized
- Different schemes have problems with one or more of the following:
  - Sensitivity to noise and outliers
  - Difficulty handling different sized clusters and convex shapes
  - Breaking large clusters

© Tan. Steinbach, Kumar Introduction to Data Mining

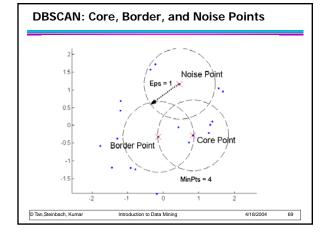

### **DBSCAN**

- DBSCAN is a density-based algorithm.
- Density = number of points within a specified radius (Eps)
- A point is a core point if it has more than a specified number of points (MinPts) within Eps
  - These are points that are at the interior of a cluster
- A border point has fewer than MinPts within Eps, but is in the neighborhood of a core point
- A noise point is any point that is not a core point or a border point

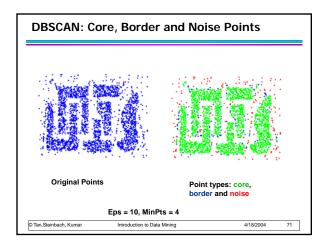

© Tan,Steinbach, Kumar

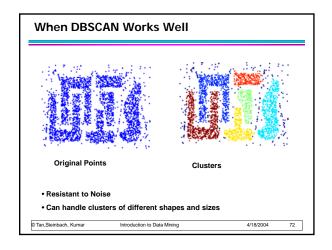

Introduction to Data Mining

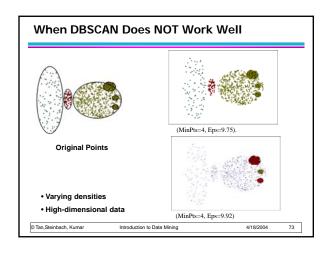

4/18/2004

### **DBSCAN Algorithm** Eliminate noise points Perform clustering on the remaining points $current\_cluster\_label \leftarrow 1$ for all core points do ${\bf if}$ the core point has no cluster label ${\bf then}$ $current\_cluster\_label \leftarrow current\_cluster\_label + 1$ Label the current core point with cluster label $current\_cluster\_label$ end if for all points in the Eps-neighborhood, except $i^{th}$ the point itself do if the point does not have a cluster label then Label the point with cluster label $current\_cluster\_label$ end for Introduction to Data Mining © Tan, Steinbach, Kumar 4/18/2004 70

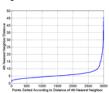

### **DBSCAN: Determining EPS and MinPts**

- Idea is that for points in a cluster, their k<sup>th</sup> nearest neighbors are at roughly the same distance
- Noise points have the k<sup>th</sup> nearest neighbor at farther distance
- So, plot sorted distance of every point to its k<sup>th</sup> nearest neighbor

### **Measures of Cluster Validity**

- The validation of clustering structures is the most difficult task
- To evaluate the "goodness" of the resulting clusters, some numerical measures can be exploited
- Numerical measures are classified into two main classes
  - External Index: Used to measure the extent to which cluster labels match externally supplied class labels.
  - e.g., entropy, purity
  - Internal Index: Used to measure the goodness of a clustering structure without respect to external information.
    - e.g., Sum of Squared Error (SSE), cluster cohesion, cluster separation, Rand-Index, adjusted rand-index

entropy For each cluster, the class distribution of the data is calculated first, i.e., for cluster j we compute  $p_{i,j}$  the 'probability' that a member of cluster j belongs to class i as follows:  $p_{i,j} = m_{i,j}/m_{j,j}$  where  $m_{i,j}$  is the number of values in cluster j and  $m_{i,j}$  is the number of values of class i in cluster j. Then using this class distribution, the entropy of each cluster j is calculated using the standard formula  $e_{i,j} = \sum_{i=1}^{n} p_{i,j} e_{i,j}$ , where the j is the number of classes. The total entropy for a set of clusters is calculated as the sum of the entropies of each cluster weighted by the size of each cluster, i.e.,  $e = \sum_{i=1}^{K} \frac{m_{i,j}}{m_{i,j}}$ , where  $m_{j}$  is the size of cluster j, j, j, j is the number of clusters, and m is the total number of data points.

**purity** Using the terminology derived for entropy, the purity of cluster j, is given by  $purity_j = \max p_{ij}$  and the overall purity of a clustering by  $purity = \sum_{i=1}^K \frac{m_i}{m_i} purity_j$ .

© Tan, Steinbach, Kumar Introduction to Data Mining 4/18/2004 76

### **Internal Measures: Cohesion and Separation**

- Cluster Cohesion: Measures how closely related are objects in a cluster
  - Cohesion is measured by the within cluster sum of squares (SSE)

$$WSS = \sum_{i} \sum_{x \in C_i} (x - m_i)^2$$

- Cluster Separation: Measure how distinct or wellseparated a cluster is from other clusters
  - Separation is measured by the between cluster sum of squares

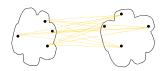

$$BSS = \sum_{i} |C_{i}| (m - m_{i})^{2}$$

© Tan, Steinbach, Kumar Introduction to Data Mining 4/18/2004 77

### **Internal Measures: Cohesion and Separation**

- A proximity graph based approach can also be used for cohesion and separation.
  - Cluster cohesion is the sum of the weight of all links within a cluster.
  - Cluster separation is the sum of the weights between nodes in the cluster and nodes outside the cluster.

cohesion

separation

### **Final Comment on Cluster Validity**

"The validation of clustering structures is the most difficult and frustrating part of cluster analysis.

Without a strong effort in this direction, cluster analysis will remain a black art accessible only to those true believers who have experience and great courage."
